Main implementation risks and gaps

1. **Keyboard failure criteria need sharper definitions.** FR-03 lists keys and asks the system to distinguish traps from valid modal focus containment, but doesn't define how many navigation attempts or what focus behavior constitutes a trap. TC2 also needs a repeatable definition of a keyboard-inoperable control.
2. **Contrast sampling needs a measurement method.** The PRD requires actual screenshot pixels but leaves open how to isolate background pixels from text, antialiasing, overlays, gradients, and image variation. "Sample multiple relevant background pixels" in the risk table is not yet an algorithm or acceptance rule.
3. **The WCAG scope is underspecified.** The product accepts A, AA, or AAA, but only provides AA contrast thresholds. It should define how the chosen level affects rule selection and what happens when a check cannot assess a criterion. The PRD should also make clear that results cover only the checks actually performed, not overall conformance.
4. **Retest equivalence needs a stable definition.** "Same page" and "same relevant checks" may be ambiguous if the page changes or the original check depended on browser state. A retest should retain the original URL and check configuration, and record whether it could reproduce the relevant conditions.
5. **The data model is missing workflow details.** It does not fully define proposed versus approved findings, rejection/edit history, duplicate matching, incomplete check results, or status transition records. These affect the approval and audit-trail requirements.
6. **The API table is malformed and incomplete.** The endpoint and method columns are misaligned, and response formats, error behavior, and idempotency are not specified. The API is described as required, but there is no corresponding acceptance criterion for each endpoint.
7. **"AI agent" is not tied to a necessary AI capability.** The optional AI integration is correctly nonessential, but the core workflow is largely deterministic browser automation. The PRD should explain what makes the

product agentic, or describe it as an accessibility auditing application with an orchestrated workflow.

8. **Deployment and demo assumptions are thin.** The PRD calls for a deployed application and reproducible test cases, but does not specify fixture hosting, browser/runtime constraints, evidence retention, or a clean-start demo procedure. These are likely to matter under hackathon time pressure.
